
Marine-adapted species (procellariiforms, larids, alcids, divers, penguins)	Large-bodied generalists (corvids, waterfowl, raptors)	Small-bodied passerines and nearshore insectivores
Pelagic and coastal marine environments	Terrestrial and wetland interfaces	Terrestrial, riparian, and coastal interfaces
Low MP accumulation despite direct plastic exposure	High MP accumulation linked to human association	Elevated MP accumulation despite small body size
Efficient regurgitation (procellariiforms) or rapid gastric passage	Commensal behavior increases exposure to urban and agricultural plastic pollution	Frequent prey ingestion in habitats where plastics accumulate (freshwater–marine interfaces)
Globally consistent pattern across diverse marine specialists	Human-modified landscapes drive elevated MP risk across diverse avian orders	Small body size does not buffer against MP exposure; habitat and foraging mode are stronger determinants
